

Lecture 8.3 - Supervised Learning Neural Networks - Losses

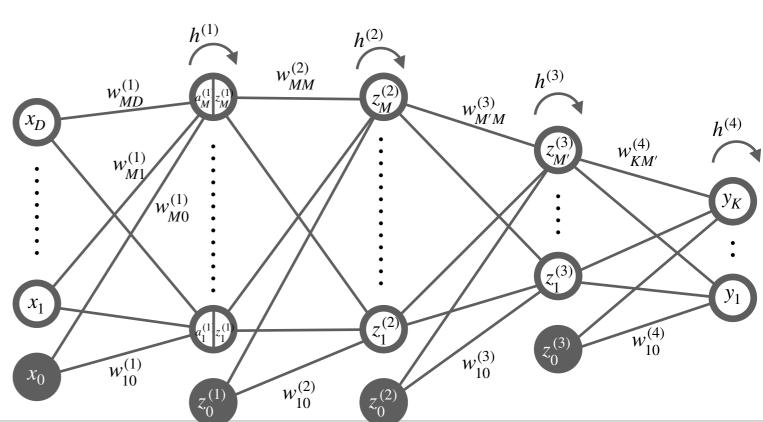

Erik Bekkers

(Bishop 5.2.0)

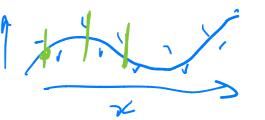

## **Network Training**

- Dataset: inputs  $\mathbf{X} = (\mathbf{x}_1, ..., \mathbf{x}_N)^T$   $\mathbf{x}_n \in \mathbb{R}^D$
- Use a probabilistic interpretation of the network outputs to choose
  - 1. Number of outputs
  - 2. Output activation function
  - 3. Loss function!

# Network Training: Regression

- Data: inputs  $\mathbf{X} = (\mathbf{x}_1,...,\mathbf{x}_N)^T$ , and targets  $\mathbf{t} = (t_1,...,t_N)^T$ X GIR
- Assume target distribution:  $p(t|\mathbf{x}, \mathbf{w}) = \mathcal{N}(t \mid g(\mathbf{x}, \mathbf{w}), \beta^{-1})$
- Single target —> Single output unit:  $y(\mathbf{x}, \mathbf{w}) = h^{(L)}(a^{\text{out}})$
- Targets are real valued: identity output activation function:

$$y(\mathbf{x}, \mathbf{w}) = h^{(L)}(a^{\text{out}}) = a^{\text{out}}$$

Maximum Likelihood/minimum negative log likelihood:

$$E(\mathbf{w}) = -\ln p(\mathbf{t}|\mathbf{X}, \mathbf{w}) = \frac{\beta}{2} \sum_{n=1}^{N} \{y(\mathbf{x}_n, \mathbf{w}) - t_n\}^2 - \frac{N}{2} \ln \beta + \frac{N}{2} \ln 2\pi$$

Equivalently: 
$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \{y(\mathbf{x}_n, \mathbf{w}) - t_n\}^2$$

## Network Training: Binary Classification

- Pata: inputs  $\mathbf{X}=(\mathbf{x}_1,...,\mathbf{x}_N)^T$ , and targets  $\mathbf{t}=(t_1,...,t_N)^T$   $\underbrace{\mathbf{X}}_{\mathbf{n}} \in \mathbb{R}^p \qquad \text{ww}$
- Assume target distribution:  $y(\mathbf{x}, \mathbf{w}) = p(t = 1 | \mathbf{x})$   $p(t | \mathbf{x}, \mathbf{w}) = y(\mathbf{x}, \mathbf{w}) \cdot (1 y(\mathbf{x}, \mathbf{w})) \cdot t$ 
  - Single target —> Single output unit:  $y(\mathbf{x}, \mathbf{w}) = h^{(L)}(a^{\text{out}})$
  - Targets are binary: sigmoid output activation function:

$$\mathsf{pot}(\mathbf{x}, \mathbf{w}) = h^{(L)}(a^{\mathrm{out}}) = \sigma(a^{\mathrm{out}}) \quad \boldsymbol{\varepsilon} \quad \mathsf{vol}$$

Maximum Likelihood/minimum negative log likelihood:

$$E(\mathbf{w}) = -\sum_{n=1}^{N} \epsilon_n \ln y(\underline{x}_n, \underline{w}) + (1-\epsilon_n) \ln(1-y(\underline{x}_n, \underline{w}))$$

Machine Learning 1

## Network Training: Classification with K classes

- Assume target distribution:  $p(\mathbf{t}_n|\mathbf{x}_n,\mathbf{w}) = \prod_{k=1}^{K} y_k(\mathbf{x}_n,\mathbf{w})^{t_nk}$   $y_k(\mathbf{x},\mathbf{w}) = p(\mathcal{C}_k|\mathbf{x})$
- K targets —> K output units:  $y_k(\mathbf{x}, \mathbf{w}) = h^{(L)}(a_k^{\text{out}})$   $(C_k \mid \mathbf{x}) = \mathbf{y}_k (\mathbf{x}, \mathbf{w}) = \mathbf{y}_k$ Categorical targets: softmax output activation function
  - $y_k(\mathbf{x}, \mathbf{w}) = h^{(L)}(\mathbf{a}^{\text{out}}) = \frac{\exp(a_k^{\text{out}})}{\sum_{i=1}^K \exp(a_i^{\text{out}})}$
  - Maximum Likelihood/minimum negative log likelihood:

$$E(\mathbf{w}) = -\sum_{h=1}^{N} \sum_{k=1}^{K} b_{nk} l_{n} U_{k} (X_{n}, W)$$

### Losses overview

#### To minimize

- Regression
  - Assume Gaussian target distribution
  - NN makes prediction for the mean
  - Output activation is identity
- Binary classification
  - Assume Bernoulli target distribution
  - NN makes prediction for probability for class 1
  - Output activation is logistic sigmoid
- Multi-class classification
  - Assume generalized Bernoulli target distribution
  - NN makes prediction for probability for each class
  - Output activation is soft max function

Least squares errors

Cross-entropy loss

(Multi-class) Cross-entropy loss
